

Interview ID	Main pattern	Most common codes	Contradictions or surprises	Link to window case	Link to risk pathways	Limitation
INT-01	The supplier interview shows that practical repairability depends strongly on component access, available spare parts and client willingness to repair rather than replace.	Component accessibility, Repair, Component replacement, Spare parts, Premature replacement, User acceptance, Implementation gap, Lifecycle verification	The supplier had strong practical repair knowledge but limited information about verified service life or environmental impact. He also did not identify replaceable parts as a source of extra technical complexity.	Supports the VELFAC case by showing why access to hardware, seals, glazing units and spare parts matters for product-life extension. It also supports the identified uncertainty around spare-part availability and use-phase information.	Supports pathways about accessible repair, missing spare parts, premature replacement, project-specific reuse barriers and missing lifecycle verification.	Single supplier perspective. Findings are exploratory and not validated.
INT-02	The architect interview shows that repairability is shaped by specification, installation method, dimensional standardisation, client briefs and regulatory context.	Component replacement, Component accessibility, Design intervention, Disassembly, Implementation gap, Lock-in, Standardisation, Lifecycle verification, Regulation	The architect suggested that supplier information may be available when requested, so the problem is partly information flow and adoption in practice rather than complete absence of information.	Supports the VELFAC case by showing that a window product cannot be assessed separately from its wall interface, installation strategy, dimensions and future access conditions.	Supports pathways about technological lock-in, difficult future replacement, standardisation barriers, higher initial complexity and the need for clear design requirements.	Single architect perspective. Findings are exploratory and not validated.
Combined	Both interviews show that repairability is not only a product feature. It depends on access, installation, spare parts, standardisation, information flow, client expectations and wider decision-making conditions.	Component accessibility, Component replacement, Design intervention, Implementation gap, Premature replacement, Direct reuse, Lifecycle verification, Standardisation	Both experts did not provide direct examples of sustainable-looking window decisions creating unexpected problems later. Therefore the interviews support implementation-gap and repairability findings more strongly than direct rebound examples.	Together, the interviews strengthen the VELFAC case by showing that the system's repairability cannot be judged only from product documentation. Practical conditions such as access, spare parts, dimensions and installation method remain decisive.	The combined findings can be translated into risk pathways for inaccessible components, unavailable parts, premature replacement, made-to-measure reuse barriers, higher-complexity systems and missing lifecycle information.	Two exploratory expert perspectives. Useful for triangulation but not representative or validated.
