

Framework element	Initial version	Practitioner feedback	Revision	Revision status	Reason for revision
Framework title	Circular Window Component and Rebound-Risk Check	The title and framework were understandable	No change required	Reviewed - no revision required	The practitioner found the framework understandable
Overall structure	Eight screening questions covering function, component failure, independent replacement, practical repair, actors, trade-offs, rebound or displacement, and lifecycle plausibility	The framework can be used in practice and no question was identified as unrealistic	No structural change required	Reviewed - no revision required	The eight-question structure remained practical and complete
Q1 Function preserved	What function must the window system preserve over the study period?	No difficulty identified	No change required	Reviewed - no revision required	The question supports fair comparison between repair, replacement and life-extension strategies
Q2 Short-life components	Which components are likely to fail before the whole window reaches end of life?	No difficulty identified	No change required	Reviewed - no revision required	The question remains useful for identifying component-level failure before full-system replacement
Q3 Independent replacement	Can short-life components be replaced independently without replacing the complete window?	No difficulty identified	No change required	Reviewed - no revision required	The question remains useful for testing technical repairability
Q4 Practical repair enabled	Is repair practically enabled by access, installation method and maintenance infrastructure?	No difficulty identified	No change required	Reviewed - no revision required	The question remains important because repairability depends on real project conditions
Q5 Actor support	Which actors must support the strategy over time?	No difficulty identified	No change required	Reviewed - no revision required	The question remains useful for clarifying responsibility across the supply chain
Q6 Trade-offs	What trade-offs are introduced by the circular strategy?	No difficulty identified	No change required	Reviewed - no revision required	The question remains useful for avoiding automatic sustainability claims
Q7 Rebound or displacement	Could the strategy trigger rebound, displacement or unintended replacement behaviour?	The practitioner confirmed that the framework distinguishes rebound risks from ordinary implementation problems	No change required	Reviewed - no revision required	The classification logic was understandable to the practitioner
Q8 Lifecycle plausibility	Is the expected lifecycle benefit still plausible after assumptions and uncertainties are considered?	No difficulty identified	No change required	Reviewed - no revision required	The question remains useful for connecting the framework to transparent assumptions
Project stage	The framework was initially described as an early screening tool	The practitioner stated that it can be used at any project stage, is best used at the beginning, and can also be applied to an already started project	Clarify that the framework is best used early, but can also support later review in already-started projects	Revised	This improves the practical positioning of the framework

Information availability	The framework asks architects to check product, repair, actor and lifecycle conditions	The practitioner stated that an architect would have enough information to use the framework	No change required	Reviewed - no revision required	The feedback supports practical usability
Missing elements	The framework included eight questions and classification categories	The practitioner did not identify anything important as missing	No change required	Reviewed - no revision required	No additional question was needed
Claim wording	Practitioner-reviewed preliminary framework, not validated	The feedback was positive but came from one practitioner only	Keep claim wording unchanged	Reviewed - no revision required	The framework must not be presented as validated
Final usability note	The framework is an early screening tool, not a complete LCA or final decision model	The practitioner feedback supports practical use, especially at the beginning of a project	Clarify that the framework is preliminary, practitioner-reviewed and best used early, while remaining usable later as a review tool	Revised	This keeps the claim practical but honest
