

Section	Text
Purpose of Step 15	The preliminary framework was shown to one practitioner who had also participated in the expert interviews. The purpose of this feedback round was to check whether the framework was understandable, whether it could be used in architectural practice, which questions might be unrealistic, what information an architect would realistically have, what was missing, and whether the framework distinguished rebound-related risks from ordinary implementation problems.
Practitioner reviewed status	Because the framework was reviewed by one practitioner, it can be described as a practitioner-reviewed preliminary framework. It should not be described as validated.
Feedback received	The practitioner stated that the framework is understandable. He indicated that it can be used at any project stage, although it would be best used at the beginning of a project and can also be applied to an already started project. He did not identify any question as unrealistic or difficult to answer, stated that an architect would have enough information to use it, did not identify missing elements, and confirmed that the framework distinguishes rebound risks from ordinary implementation problems.
How feedback was used	The feedback did not require structural changes to the framework. The main revision was to clarify the practical positioning of the framework: it is best used early in the project, but it may also support review and decision-making in later or already-started projects.
Claim level	The feedback process improves the practical relevance of the framework, but it does not prove effectiveness, reliability or wider applicability. The result remains exploratory and preliminary.
Limitation wording	The practitioner feedback was limited to one expert perspective and should be interpreted as a practical review rather than formal validation. Further testing with additional architects, suppliers, contractors, maintenance specialists and manufacturers would be required before the framework could be considered validated.
Final report wording	The Circular Window Component and Rebound-Risk Check was reviewed by one practitioner to assess clarity and practical usability. The feedback confirmed that the framework was understandable, usable in architectural practice, and able to distinguish rebound-related risks from ordinary implementation problems. The practitioner suggested that the framework is best used at the beginning of a project, although it can also be applied to already-started projects. The framework is therefore practitioner-reviewed, but not validated.
